Abstract

Objective: Although clinical hyperthyroidism (HR) is associated with insulin resistance, the information on insulin action in subclinical hyperthyroidism (SHR) is limited.

Design and methods: To investigate this, we assessed the sensitivity of glucose metabolism to insulin in vivo (by an oral glucose tolerance test) and in vitro (by measuring insulin-stimulated rates of glucose transport in isolated monocytes) in 12 euthyroid subjects (EU), 16 patients with HR, and 10 patients with SHR.

Results: HR and SHR patients displayed higher postprandial glucose levels (area under the curve, $A_{UCD_{0-100}}$ 32 190 ± 1067 and 31 497 ± 716 mg/dl min respectively) versus EU (27 119 ± 1156 mg/dl min, $P < 0.05$). HR but not SHR patients displayed higher postprandial insulin levels ($A_{UCD_{0-100}}$ 11 020 ± 985 and 9565 ± 904 mU/l min respectively) compared with EU subjects ($A_{UCD_{0-100}}$ 7 588 ± 743 mU/l min, $P < 0.05$). Homeostasis model assessment index was increased in HR and SHR patients (2.81 ± 0.3 and 2.43 ± 0.38 respectively) compared with EU subjects (1.27 ± 0.16, $P < 0.05$), while Matsuda and Belfiore indices were decreased in HR (4.21 ± 0.41 and 0.77 ± 0.05 respectively, $P < 0.001$) and SHR patients (4.47 ± 0.33 and 0.85 ± 0.05 respectively, $P < 0.05$ versus EU (7.76 ± 0.87 and 1 respectively). At 100 μU/ml insulin, i) GLUT3 levels on the monocyte plasma membrane were increased in HR (468.8 ± 7 mean fluorescence intensity (MFI)) and SHR patients (522.2 ± 25 MFI) compared with EU subjects (407 ± 18 MFI, $P < 0.01$ and $P < 0.05$ respectively), ii) glucose transport rates in monocytes (increases from baseline) were decreased in HR patients (37.8 ± 5%) versus EU subjects (61.26 ± 10%, $P < 0.05$).

Conclusions: Insulin-stimulated glucose transport in isolated monocytes of patients with HR was decreased compared with EU subjects. Insulin resistance was comparable in patients with both HR and SHR.

Introduction

In clinical hyperthyroidism (HR), impaired glucose tolerance and insulin resistance are frequent findings (1–5). In HR, tissue metabolic rate increases significantly (1). To adapt to high energy demand, cellular rates of basal and insulin-stimulated glucose disposal are generally elevated to increase the rates of lactate formation and glucose oxidation; lactate is then used by the liver to increase the rates of gluconeogenesis and endogenous glucose production (1, 2).

Subclinical hyperthyroidism (SHR) is defined as decreased plasma TSH levels in the presence of normal levels of free thyroxine ($FT_4$) and free triiodothyronine ($FT_3$). SHR can be caused by exogenous or endogenous factors (6) and may be transient or persistent. The studies in the literature regarding insulin resistance in SHR are scarce and controversial. Insulin sensitivity in patients with iatrogenic SHR has been reported to be either reduced (7, 8) or unaltered (9).

In SHR subjects, relevant changes in cardiovascular measures, such as arrhythmias, increased left ventricular mass, and impaired left ventricular mass function, have been recently reported; these changes are often accompanied by impaired diastolic function and, sometimes by reduced systolic performance on effort and decreased exercise tolerance, abnormalities that usually precede the onset of severe cardiovascular disease (10).

This study was undertaken in patients with HR and SHR to examine the sensitivity of glucose metabolism to insulin both in vivo (by an oral glucose tolerance test (OGTT)) and in vitro (by measuring insulin-stimulated rates of glucose transport in isolated monocytes).
Materials and methods

Subjects

The groups participating in the study were i) newly diagnosed clinical hyperthyroidism (HR) subjects with Graves’ disease who received no treatment, ii) patients with SHR; these patients had autoimmune thyroiditis due to positive thyroid antibodies, and iii) euthyroid subjects (EU). There were no statistically significant differences in either body mass index or age between EU and HR and SHR groups (P > 0.05, with one-way ANOVA). The characteristics and the hormonal and metabolic data of the groups are presented in Table 1. None of the subjects was receiving any treatment or had a family history of type 2 diabetes. The female participants were at the first half of their menstrual cycle, and no one was taking oral contraceptives. None of the subjects was receiving any treatment or had a family history of type 2 diabetes. The female participants were at the first half of their menstrual cycle, and no one was taking oral contraceptives.

The duration of the disease, as reported by HR patients, could not be accurately defined, as it is mostly asymptomatic. The normal ranges for hormones were FT₃ 2.2–5.3 pg/ml, FT₄ 0.7–2.2 ng/dl, T₃ 0.8–2.0 ng/ml, T₄ 5.1–14.1 µg/dl, and TSH 0.27–4.2 µU/ml. Anti-thyroglobulin (anti-TG) and anti-thyroperoxidase (anti-TPO) antibodies’ reference ranges were <34 and <115 U/ml respectively. EU subjects had negative anti-TG and anti-TPO antibodies (10.9 ± 5.3 and 15.6 ± 3.2 U/ml respectively), while these antibodies were positive in both HR (231 ± 83 and 218 ± 147 U/ml respectively) and SHR (226 ± 100 and 213 ± 103 U/ml respectively).

Some of the EU volunteers of the present study were used in a similar study published recently by our group (11). The protocol was approved by the hospital ethics committee, and subjects gave informed consent.

Study protocol

Subjects were admitted to the hospital at 0800 h after an overnight fast and received an OGTT (75 g glucose). Blood samples were drawn before the administration of glucose (at −30 and 0 min) and at 15- to 60-min intervals for 300 min thereafter, and used for measurements of glucose (Yellow Springs Instrument, Yellow Springs, OH, USA) and insulin (RIA, Linco Research, St Charles, MO, USA)

In the fasting state, insulin resistance was estimated by the homeostasis model assessment index (HOMA, (fasting glucose × fasting insulin/22.5)) (12), while in the post-glucose state, insulin sensitivity was estimated by the Matsuda index (10 000/SQRT(mean glucose₀–120 × mean insulin₀–120 × fasting glucose × fasting insulin)) (13) and the Belfiore index (2/(GluAUC₀–120/meanGluAUC₀–120×fasting insulin)) (14)

At −30 min, 20 ml of blood were drawn for the isolation of mononuclear cells to assess i) GLUT3 and GLUT4 glucose transporter levels on the monocyte plasma membrane in response to insulin, and ii) insulin-stimulated rates of glucose transport.

**Effect of insulin on GLUT expression and 6-[N-(7-nitrobenz-2-oxa-1, 3-diazol-4-yl) amino]-6-deoxyglucose uptake: flow cytometry analysis**

Insulin exerts its action at a cellular level by numerous steps of intracellular mechanism, the insulin signaling pathway. Regarding glucose transport, the final step
of insulin signaling is the enrichment of plasma membrane with GLUT3 and GLUT4 isoforms. Surface glucose transporter isoforms were determined after incubating cells with insulin and staining them with anti-GLUT antigens. In summary, mononuclear cells were aliquoted at the desired concentration (1×10⁶ cells/ml) and incubated for 60 min, at 22°C, in a buffer (NaCl 140 mM, HEPES 20 mM, KCl 5 mM, MgSO₄ 2.5 mM, and glucose 5.5 mM, pH 7.4), containing different concentrations of insulin (Sigma Diagnostics). Termination of incubation was achieved with the addition of cytochalasin-B (10 μM; Sigma Diagnostics). Cells were then stained with specific antiserum for GLUT3 and GLUT4, and were analyzed by flow cytometry as described previously in detail (15).

For the glucose transport experiments, the tracer used to monitor glucose flux in monocytes was 6-(7-nitrobenz-2-oxa-1, 3-diazol-4-yl) amino]-6-deoxyglucose (NBDG, Invitrogen). Cells were suspended in the above-mentioned buffer at the same concentration (30 μM) and insulin. The uptake of the fluorescent probe was recorded as mean fluorescence intensity (MFI) during a 500 s interval, when the reaction reached a plateau (15).

**Statistical analysis**

Grouped data are expressed as mean± S.E.M. 6-NBDG uptake is presented as an increase over baseline (MFI of cells prior to the addition of the fluorescent analog). The statistical analysis was performed by the statistic software GraphPad InStat (San Diego, CA, USA). The normal distribution of the data was verified by the Kolmogorov and Smirnov method. Insulin dose–response curves were analyzed with repeated-measures ANOVA. The respective increases for the SHR patients was 12% (from 194 to 270 MFI) and by 34% (from 301 to 403 MFI) respectively (P<0.0001 with ANOVA for both). The respective increases for the HR patients was 13% (from 318 to 360 MFI, P=0.001 with ANOVA) and 21% (from 388 to 469 MFI, P<0.0001 with ANOVA), while the respective increases for the SHR patients was 12% (from 252 to 309 MFI, P=0.049 with ANOVA) and 22.8% (from 466 to 522 MFI, P=0.021 with ANOVA; Fig. 2).

At 100 μU/ml insulin, GLUT4 levels on the monocyte plasma membrane increased in the HR patients (360 MFI) versus EU subjects (270 MFI, P<0.05), while GLUT3 levels increased in both HR (403 MFI) and SHR patients (522 MFI) compared with EU subjects (403 MFI, P<0.05; Fig. 2).

In monocytes from EU subjects, when insulin was increased from 0 to 100 μU/ml, GLUT4 and GLUT3 isoforms on the plasma membrane increased by 39% (from 194 to 270 MFI) and by 34% (from 301 to 403 MFI) respectively (P<0.0001 with ANOVA for both). The respective increases for the HR patients was 13% (from 318 to 360 MFI, P=0.001 with ANOVA) and 21% (from 388 to 469 MFI, P<0.0001 with ANOVA), while the respective increases for the SHR patients was 12% (from 252 to 309 MFI, P=0.049 with ANOVA) and 22.8% (from 466 to 522 MFI, P=0.021 with ANOVA; Fig. 2).

Postprandial plasma insulin levels were increased in HR patients compared with EU subjects (P<0.05). Postprandial plasma glucose levels were higher in both HR and SHR patients compared with EU (P<0.0001 and P<0.01 respectively).

In monocytes from EU subjects, the 6-NBDG uptake (increases from baseline) in the presence of 0, 25, and 100 μU/ml insulin was increased by 19, 43, and 62% respectively (P<0.005; Fig. 3). The respective increases for HR patients were 26, 34, and 37.8% (P<0.001), while the respective increases for SHR patients were 29.6, 36, and 49.5% (P<0.001; Fig. 3).

At 100 μU/ml insulin, the 6-NBDG uptake in monocytes from HR patients was decreased compared with EU subjects (P<0.05, Fig. 3), while there was no significant change in the monocytes isolated from SHR patients.
Discussion

Our results demonstrate the presence of insulin resistance not only in HR but also in SHR patients. Increased HOMA and decreased Matsuda and Belfiore indices in HR and SHR patients compared with euthyroid subjects suggest that insulin resistance is present in both fasting and post-glucose state. Our results are in agreement with those of Yavuz et al. (7, 8) reporting significantly lower insulin sensitivity in a group of SHR. Interestingly, recent studies have shown that even subtle decreases in the levels of thyroid hormones within the physiological range negatively correlate with the HOMA index (16). These findings, taken together with the results of the present study, suggest that even small deviations from thyroid hormone equilibrium may eventually lead to insulin resistance.

Monocytes provide an easily accessible and reliable model for metabolic studies. These cells have insulin receptors that quickly respond to changes in insulin concentrations and, in the presence of insulin rapidly increase their rates of glucose disposal (15, 17, 18). Moreover, monocytes express all GLUT isoforms found in muscle and adipose tissue, and the increases in glucose transport in response to insulin in these cells correspond well with those observed in tissues quantitatively important for glucose disposal (15, 19).

We have previously used monocytes as a cellular model to study insulin sensitivity (11, 15); furthermore, we have suggested the important role of GLUT3 in compensating increased tissue demand for glucose in the HR state (20, 21).

Our data show an elevated basal abundance of GLUT4 and GLUT3 in HR and SHR patients. This is consistent with previous studies on HR patients (20, 21). The increment in expression of GLUT3 and GLUT4 glucose transporters at the basal level of insulin reflects the adaptation of the monocyte to cope with the increased metabolic rates involved in this condition.

In monocytes isolated from HR patients, maximal insulin levels induced an increased GLUT3 and GLUT4 abundance on the monocyte plasma membrane compared with EU subjects; the response in the monocytes isolated from SHR patients was intermediate to that of HR patients and EU subjects (Fig. 2). GLUT3 is not the main insulin-regulated transporter in tissues, but as has been shown (22, 23), the expression of this isoform increases several fold in metabolic stress and increased tissue energy demand; under these conditions, this glucose transporter becomes primarily responsible for the increase in cellular glucose transport and utilization.

Glucose transport controls the rate of glucose utilization and is therefore an important regulatory step in cell metabolism (24). In HR, the absolute rates of insulin-stimulated glucose transport in peripheral tissues (such as muscle or adipose tissue) have generally been found to be normal or increased, in order to adapt to high energy demand (3, 25). However, we have recently shown that glucose uptake in muscle in HR is indeed resistant to insulin, but this defect is masked by a marked increase in blood flow (4); this could be attributed to the dramatic decrease in intracellular pathways of insulin-stimulated glucose metabolism.

Figure 2

Plasma membrane levels of GLUT4 (A) and GLUT3 (B) in isolated monocytes in the presence of physiological concentrations of insulin in euthyroid (EU) subjects, and patients with clinical hyperthyroidism (HR) and subclinical hyperthyroidism (SHR); *P<0.05, **P<0.01 versus EU.

Figure 3

Transport rates of glucose analog (6-NBDG) in isolated monocytes in the presence of physiological concentrations of insulin in euthyroid (EU) subjects, and patients with clinical hyperthyroidism (HR) and subclinical hyperthyroidism (SHR); *P<0.05 versus EU. 6-NBDG uptake is presented as an increase over baseline (MFI of cells prior to 6-NBDG addition).
recently shown that the elevated levels of T3 in HR intracellular concentration of calcium. It has been insulin-stimulated glucose uptake in the monocytes of between the abundance of GLUT3 and GLUT4 and the from HR and SHR patients. The lack of correlation abundance of insulin-stimulated GLUT3 and GLUT4 in striking contrast with the significantly increased thyroid hormones in our SHR group). This result comes further supported by the intermediate levels of the metabolic condition between EU and HR (which is further supported by the intermediate levels of the thyroid hormones in our SHR group). This result comes in striking contrast with the significantly increased abundance of insulin-stimulated GLUT3 and GLUT4 glucose transporters observed in monocytes isolated from HR and SHR patients. The lack of correlation between the abundance of GLUT3 and GLUT4 and the insulin-stimulated glucose uptake in the monocytes of the HR patients could be attributed to elevated intracellular concentration of calcium. It has been recently shown that the elevated levels of T3 in HR increase calcium concentration in the cytosol (28). Elevated levels of cytosolic calcium can modulate insulin’s ability to desphosphorylate GLUT4, thus reducing its intrinsic activity and resulting in calcium-induced insulin resistance (29).

In conclusion, HR and SHR are both states of insulin resistance. Both insulin resistance and the increased abundance of GLUT3 and GLUT4, on monocyte plasma membrane of SHR, which were found intermediate to those of HR and EU, are likely explained by the different degrees of thyroid hormone levels. Future research should focus on the insulin signaling cascade and the plausible association of impairment of phosphorylation pattern of signaling molecules (such as insulin receptor substrate 1) with decreased glucose uptake.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research reported.
